

A GLIMPSE · PRODUCT BRIEFING

Northstar SellerOS

Seller-side real-estate intelligence, built for Canada.
Autonomous on the inside. Human-approved on the outside.

Bilingual EN / fr-CA · Ontario-first · consent-first · every action gated, logged, and explainable.

Now opening a **supervised demo pilot**.

A five-minute read. No technical background needed. Demo data is fictional; nothing here is a production claim.

01 — The idea, in one breath

Selling a home is a chain of high-stakes decisions — pricing, positioning, offers, conditions, deadlines. Northstar SellerOS is an operating system that lets software agents do the heavy lifting on that chain, while a licensed human keeps both hands on the wheel.

It is built specifically for Canadian real estate: bilingual from the ground up (English and fr-CA), Ontario-first in its rules, and consent-first in its data. It is not a chatbot bolted onto a spreadsheet — it is a governed workspace where autonomous cores prepare the work and people approve the moves.

What it actually does for a seller

Understands the property

Builds a living dossier: facts, evidence, comparables, and a defensible valuation narrative.

Shapes the strategy

Proposes pricing and positioning, with the reasoning attached — not just a number.

Reads every offer

Extracts the terms that matter and lines offers up side by side, so trade-offs are visible at a glance.

Keeps the deal moving

Turns an accepted offer into a tracked task plan — deadlines, conditions, and owners, all in one place.

The honest part: the system proposes; humans decide. Nothing leaves the building — no message, no document, no commitment — without a person's explicit approval.

02 — How one action travels

Every meaningful action follows the same guarded path. This is the whole trick, and it takes one diagram:

Whether an action sails through, waits for a signature, or gets stopped — all three endings are recorded in the same tamper-evident trail.

Why the fence is the feature

Consent is a hard rule, not a setting

If consent has expired, the send simply does not happen — the system blocks it and writes down why. That behaviour is part of the demo, not a promise slide.

Approvals can't be replayed

One approval, one use. Two people clicking at the same moment still produce exactly one decision.

Every brokerage is a sealed room

Tenants can't see or touch each other's data — enforced in the data layer and covered by dedicated tests.

03 — Trust, but verified

Anyone can demo a confident prototype. So the pilot was held to a simple standard: if it can't be executed, it doesn't get claimed. A few numbers from the verification battery:

Executed, repeatable checks — run twice end-to-end, plus independent re-verification from a fresh copy of the release.

Behind those bars sit a few deliberate engineering choices: an **append-only audit log** where each entry is cryptographically chained to the one before it; an **outbox** that guarantees no message is ever sent twice, even across a crash and restart; and a rule that **tests may never be loosened to make a result look green**.

What the numbers don't mean: they don't make it a finished product. They mean the foundation under the pilot is measured, not vibes.

04 — What's real today, what's next

The vision is a fleet of twenty specialised agent cores. Today, three are live and demonstrable — and we say so plainly, because a pilot built on honesty scales better than one built on theatre.

Live today: lead conversations, offer extraction, transaction coordination. The rest is roadmap — sequenced, not vapour.

Deliberately not claimed

Live integrations with external services (today they are safe mocks) · legal or regulatory certification · unsupervised autonomy · production readiness. When any of these change, it will be announced with evidence — the same standard this document is held to.

05 — Trying it costs an afternoon, not a quarter

The pilot is designed for low bandwidth. No data migration, no integration project, no training programme — a supervised sandbox with fictional demo data.

1

Sign in and meet Harbourline Realty

A fully fictional brokerage is pre-loaded — listings, contacts, offers, the works. Explore freely; nothing is real and nothing can leak.

2

Walk one deal end to end

Lead conversation → dossier → valuation → strategy → offers compared → transaction plan. Watch the approval desk and the blocked-message demo on the way.

3

Tell us where it earned trust — and where it didn't

The pilot's output is your verdict. What gets wired next is decided by what supervised users actually value.

The short version: autonomous where it's safe, human where it matters, honest about where it stands. If that sounds like the way real-estate software should behave — come see it work.

Northstar SellerOS · Demo pilot · Supervised Ontario testing with fictional data · Human approval gates on every external action · Bilingual EN / fr-CA.
